Conversion Factors, Datum, and Abbreviations

Multiply		By	To obtain
	liter (L)	0.2642	gallon
	microliter (μ L)	0.0002642	gallon
	micrometer (μ m)	0.0000394	inch
	millimeter (mm)	0.03937	inch
	millimeter per day (mm/day)	0.03937	inch per day

Temperature in degrees Celsius ($^{\circ}$ C) may be converted to degrees Fahrenheit ($^{\circ}$ F) as follows:

$$^{\circ}\text{F} = 1.8 \text{ }^{\circ}\text{C} + 32$$

Transmissivity: The standard unit for transmissivity is cubic foot per day per square foot times foot of aquifer thickness $[(\text{ft}^3/\text{d})/\text{ft}^2]\text{ft}$. In this report, the mathematically reduced form, foot squared per day (ft^2/d), is used for convenience.

Datum

Vertical coordinate information is referenced to the North American Vertical Datum of 1988 (NAVD 88).

Horizontal coordinate information is referenced to North American Datum of 1983 (NAD 83).

Altitude, as used in this report, refers to distance above the vertical datum.

Dissolved Pesticide and Organic Carbon Concentrations Detected in Surface Waters, Northern Central Valley, California, 2001–2002

By James L. Orlando, Lisa A. Jacobson *and* Kathryn M. Kuivila

Abstract

Field and laboratory studies were conducted to determine the effects of pesticide mixtures on Chinook salmon under various environmental conditions in surface waters of the northern Central Valley of California. This project was a collaborative effort between the U.S. Geological Survey (USGS) and the University of California. The project focused on understanding the environmental factors that influence the toxicity of pesticides to juvenile salmon and their prey. During the periods January through April 2001 and January through May 2002, water samples were collected at eight surface water sites in the northern Central Valley of California and analyzed by the USGS for dissolved pesticide and dissolved organic carbon concentrations. Water samples were also collected by the USGS at the same sites for aquatic toxicity testing by the Aquatic Toxicity Laboratory at the University of California Davis; however, presentation of the results of these toxicity tests is beyond the scope of this report. Samples were collected to characterize dissolved pesticide and dissolved organic carbon concentrations, and aquatic toxicity, associated with winter storm runoff concurrent with winter run Chinook salmon out-migration. Sites were selected that represented the primary habitat of juvenile Chinook salmon and included major tributaries within the Sacramento and San Joaquin River Basins and the Sacramento–San Joaquin Delta. Water samples were collected daily for a period of seven days during two winter storm events in each year. Additional samples were collected weekly during January through April or May in both years. Concentrations of 31 currently used pesticides were measured in filtered water samples using solid-phase extraction and gas chromatography-mass spectrometry at the U.S. Geological Survey's organic chemistry laboratory in Sacramento, California. Dissolved organic carbon concentrations were analyzed in filtered water samples using a Shimadzu TOC-5000A total organic carbon analyzer.

Introduction

Background

The study area within the northern Central Valley of California encompasses nearly 25 million acres and is drained by two major river systems, the Sacramento and the San Joaquin Rivers ([fig. 1](#)). Over five million acres within these two watersheds are devoted primarily to agriculture and produce a wide variety of crops. The area also contains numerous urban centers of varying size with a combined area of over half a million acres that support a population of over five and a half million people (U.S. Census Bureau, 2000).

During 2001, nearly 42 million pounds of pesticide active ingredient were applied in the Central Valley (California Department of Pesticide Regulation, 2001). Much of this application occurred during the winter and early spring and coincided with the region's peak annual rainfall–runoff, as well as the local, winter–spring migration of Chinook salmon. This coincidence of high use, rainfall–runoff, and salmon migration raises concern for the potential environmental effects of these pesticides.

In the Central Valley, previous studies have shown that the first significant rainfall (greater than 12.7 mm/day [0.5 in./day]) and subsequent runoff following the winter application of dormant-spray pesticides is accompanied by a rise in the detected concentrations of these same pesticides in downstream surface waters (Kuivila and Foe, 1995; Kratzer, 1997; Dubrovsky, and others, 1998). Studies have also shown these pulses of multiple pesticides to be acutely toxic to the aquatic invertebrate *Ceriodaphnia dubia* (Foe and Connor, 1991; Kuivila and Foe, 1995). However, little is known about the potential toxic effects of mixtures of pesticides on juvenile Chinook salmon or their prey.

2 Dissolved Pesticide and Organic Carbon Concentrations Detected in Surface Waters, Northern Central Valley, California

Figure 1. Study area and sampling sites in the northern Central Valley, California.

In addition, the toxicity of pesticides and other organic pollutants to aquatic species is influenced by environmental factors such as dissolved organic matter found in natural waters (Haitzer, and others, 1998). Dissolved organic matter is most commonly quantified in terms of dissolved organic carbon (DOC). The concentration and type of dissolved organic matter can influence the toxicity of the contaminant by increasing or decreasing its bioavailability to aquatic species (Kukkonen and Oikari, 1987; Benson and Long, 1991; Day, 1991; Kadlec and Benson, 1995). It is, therefore, beneficial to measure DOC concentrations when relating pesticide concentrations in natural waters to observed toxicity.

Purpose and Scope

This report describes the methods and procedures used during sample collection and analysis, and presents analysis results for water samples collected during this study. Concentrations of 31 currently (2002) used pesticides analyzed in 234 water samples are presented. DOC concentrations analyzed in 82 water samples are also presented, as are method detection limits for pesticides analyzed in this study. During the field study, the USGS was responsible for selection of sampling sites, initiation of field sampling, collection of water samples, and chemical analysis of water samples. DeltaKeeper, a nonprofit environmental monitoring group in Stockton, California, assisted with sample collection. Water samples were analyzed for dissolved pesticides and DOC at the USGS organic chemistry laboratory in Sacramento, California.

Project Design

The overall project was designed to determine the toxicity to juvenile Chinook salmon and their prey of storm-runoff events that contained elevated concentrations of multiple pesticides. Laboratory and field studies were developed to understand both the effects of exposure to mixtures of pesticides that occurred in repeated pulses and the influence of environmental factors on pesticide toxicity. This research project was a collaborative effort among the U.S. Geological Survey (USGS), the University of California at Berkeley, the University of California at Davis, and the U.S. Fish and Wildlife Service (FWS) from 2000 to 2004.

The laboratory experiments focused on understanding factors that influence toxicity to salmon and their prey. Toxicity testing protocols were developed and employed to test toxicity of pesticide mixtures to juvenile salmon and native invertebrate species that are important food sources for salmon. Other laboratory studies explored the interaction between dissolved organic matter and pesticides, and the influence of dissolved organic matter on bioavailability and toxicity.

The field study consisted of pesticide analyses and laboratory toxicity testing of surface waters collected during January through April 2001 and January through May 2002. Water samples were collected at eight sites ([fig. 1](#)) in the Sacramento and San Joaquin River Basins and the Sacramento–San Joaquin Delta and analyzed for pesticide and DOC concentrations. Water samples collected for laboratory toxicity testing were used in laboratory bioassays by U.C. Davis's Aquatic Toxicology Laboratory; however, presentation of the results of these analyses are beyond the scope of this report and are not included. The timing of field sampling corresponded with the winter–spring migration of Chinook salmon.

Acknowledgements

The authors gratefully acknowledge Patricia von Phul of the USGS and DeltaKeeper personnel for assistance with sample collection and logistical support during this project. The authors also wish to acknowledge Jacqueline Houston, Lupe Herrera, Patrick Nicholas, and Theresa Pedersen of the USGS for their many hours of laboratory work and pesticide analyses. This project was funded by the California Bay-Delta Authority (project # 99-N08) and the U.S. Geological Survey's Toxic Substances Hydrology Program.

Study Design and Methodology

Selection of Sampling Sites

Sampling sites were selected to be representative of Chinook salmon habitats. Other criteria for site selection included local agricultural practices, past and current use of pesticides, previous surface water detections of dissolved pesticides, proximity to FWS fish collection sites, and the safety of field personnel during storm conditions. In 2001, five sites were sampled: three sites within the Delta (Greens Landing, Ulatis Creek, and Middle River) and one each within the San Joaquin (Vernalis) and Sacramento River Basins (Verona) ([fig. 1](#); table 1, at the back of this report). Samples collected at three of these sites (Verona, Greens Landing, and Middle River) contained only low concentrations of pesticides and did not cause toxicity to invertebrate test organisms; therefore, these sites were replaced in 2002 by three other sites (Boyd's Pump, Knight's Landing, and Tuolumne River at Shiloh) located farther upstream in the respective watersheds, closer to areas of current pesticide application. The locations are shown in [fig. 1](#), and site information is given in table 1. Because water samples collected at Vernalis and Ulatis Creek contained elevated pesticide concentrations and caused toxicity in laboratory bioassays, these sites were sampled again in 2002.

4 Dissolved Pesticide and Organic Carbon Concentrations Detected in Surface Waters, Northern Central Valley, California

Sample Collection

Field sampling was conducted beginning in early January each year and continued through the end of April in 2001 and the end of May in 2002. Samples were collected daily during the first two major storms (rainfall greater than 12.7 mm/day [0.5 in./day]) after local application of dormant spray pesticides, and weekly during the balance of the sampling periods. Water samples were collected for analysis of dissolved pesticides and DOC and used in aquatic toxicity testing. Tables 2 and 3 show a matrix of the dates and types of samples collected at each sampling site during 2001 and 2002, respectively. The matrix shows samples collected for blanks, DOC, pesticides, and aquatic toxicity.

Pesticide Samples

Samples were collected for pesticide analysis at all sites on each sample date during the course of the study (tables 2 and 3). At all of the sites except Boyd's Pump, water samples were collected as mid-channel grabs from bridges using a weighted 3-L Teflon bottle sampler. At each site, a pre-cleaned Teflon bottle was used after having been rinsed three times with native water. All samples were collected at a depth of approximately 0.5 m. Following collection, the samples were split into fractions by manually shaking the Teflon bottle and pouring into two 1-L baked, amber glass bottles. At Boyd's Pump, 2 L of sample water were collected from the shore by using an extendable pole to submerge single 1-L amber glass bottles. All samples were immediately placed on ice and transported to the U.S. Geological Survey's organic chemistry laboratory in Sacramento.

DOC Samples

To assess the effects of dissolved organic matter on pesticide toxicity, samples were analyzed for DOC concurrently with pesticide analysis and toxicity testing. Water samples collected for pesticide and DOC analysis were split from a single grab sample with DOC samples placed into 250-mL baked, amber glass bottles and preserved on ice. Although all five sites were analyzed for DOC concentration in 2001, water samples from only one site (Ulati Creek) were determined to be acutely toxic to a test organism (*Ceriodaphnia dubia*) in laboratory bioassays and had the highest DOC concentrations. Therefore, in 2002, samples for

DOC analysis were collected only at Ulati Creek and on nearly every sampling date (table 3).

Toxicity Samples

Water samples for toxicity testing were collected generally biweekly at all eight sampling sites, but under varying schedules in order to accommodate testing schedules at the U.C. Davis Aquatic Toxicology Laboratory (tables 2 and 3). Samples were collected more frequently during storms, and collection methods varied depending on streamflow conditions. During periods of moderate streamflow, samples were collected using a specially designed, weighted polyvinyl chloride (PVC) sampler capable of submerging a 4-L, acid washed, glass container. After rinsing the sample containers three times with native water, samples were collected at a depth of approximately 0.5 m as mid-channel grabs from bridges. During periods of very low flow (water depth too shallow to submerge PVC sampler), or high flow (stream velocity too high for safe deployment of PVC sampler), samples were collected in multiple grabs using a weighted 3-L Teflon bottle sampler and then poured directly into 4-L acid washed glass containers. All samples were preserved on ice and delivered within 6 hours of collection to the U.C. Davis Aquatic Toxicology Laboratory. Samples were tested for toxicity to three aquatic invertebrates *Ceriodaphnia dubia*, *Simocephalus sp.*, and *Chironomus tentans*. Presentation of the results of these analyses is beyond the scope of this report.

Sample Processing and Analysis

Pesticide Analysis

Water samples collected for pesticide analysis were filtered through baked, 0.7- μ m glass fiber filters within 24 hours of sampling, and a surrogate compound, terbutylazine, was added to provide quantitative data on extraction efficiency. Samples were then extracted onto C8 solid-phase extraction cartridges. The cartridges were then dried using compressed carbon dioxide, frozen, and stored for up to 6 months. For analysis, the cartridges were thawed and then eluted with 9 mL of ethyl-acetate. The eluant was concentrated and analyzed for 31 pesticides using a Varian Saturn gas chromatograph-mass spectrometer (GC/MS) with ion-trap detection. Details of the analytical method are described in Kuivila and Pedersen (2003).

Four types of quality control data were collected: field equipment blanks, replicate samples, matrix spikes, and surrogate recovery. Equipment blanks accounted for 7 percent of the total number of samples analyzed in 2001 and 2 percent in 2002. None of the pesticides were detected in the blanks. Replicate samples accounted for 9 percent of the samples analyzed in 2001 and 8 percent in 2002, and the differences were less than 25 percent for all the pesticides detected. As part of the method validation, recoveries of matrix spikes were determined in 12 percent of the samples analyzed in 2001 and 11 percent in 2002, and details are listed in the method reports (Kuivila and Houston, 2003; Kuivila and Pedersen, 2003). Recovery of the surrogate, terbuthylazine, was used to assess the efficiency of each extraction. The average percent recovery and standard deviation for terbuthylazine was calculated for each year. Sample data were excluded if the recovery of terbuthylazine was outside the control limit of the annual mean plus or minus two standard deviations (K.M. Kuivila and J.R. Houston, unpub. data, 2003; K.M. Kuivila and T.L. Pedersen, unpub. data, 2003).

DOC Analysis

Water samples collected for DOC analysis were filtered in series through a 2.7- μm (Whatman GF/A) glass fiber filter, a 0.7- μm (Whatman GF/F) glass fiber filter, and a 0.45- μm polypropylene (Pall Gelman GH Polypro Membrane) filter within 24 hours of sample collection. Filtered samples were stored in baked amber glass bottles at 4°C for no longer than 1 week until analysis. DOC concentrations were analyzed using a Shimadzu TOC-5000A total organic carbon analyzer. The instrument was calibrated with potassium-hydrogen-phthalate standards prepared in organic-free water, with standard concentrations bracketing the concentrations of the samples. Aliquots of filtered sample water (4.5 mL) were acidified with 30- μL of 2N HCl and sparged with N_2 for 3 minutes to remove inorganic carbon as CO_2 . The nonpurgeable organic carbon (NPOC) was analyzed by direct injection of liquid sample into a high-temperature (680°C) combustion tube packed with Pt catalyst. The CO_2 produced by oxidation of the NPOC was detected with a nondispersive infrared photometric cell. Each value reported represents the mean of three injections of the same sample. Details of the analytical method are described in Bird and others, 2003.

No quality control samples were taken during the field study in 2001. Replicate samples and field blanks were analyzed for all sampling days in 2002. Results showed replicates to be within 10 percent agreement for all samples. Values for field blank samples were less than 3 percent of the total DOC concentration for all samples.

Dissolved Pesticide and DOC Concentrations

This report presents dissolved pesticide and DOC concentrations analyzed in water samples collected during January through April 2001 and January through May 2002. Samples were collected at eight surface water sites within the Central Valley (fig. 1). During the study, 117 water samples were analyzed in each year for 31 pesticides by GC/MS at the U.S. Geological Survey's organic chemistry laboratory in Sacramento, California. DOC concentrations were analyzed in 64 field samples in 2001 and 14 samples in 2002. Results of these analyses are presented in tables 4–15. Pesticides that were detected at concentrations below the method detection limits listed in table 16 are shown in parentheses because the values are estimates. Significant figures were determined on the basis of the rounding method as described in American Society for Testing and Materials (1993).

32 Dissolved Pesticide and Organic Carbon Concentrations Detected in Surface Waters, Northern Central Valley, California

Table 16. Method detection limits for pesticides analyzed in water samples in 2001 and 2002

[ng/L, nanograms per liter]

Pesticide	2001/2002 Method detection limit (ng/L)
Alachlor ¹	2.1
Atrazine	4.2
Azinphos-methyl ¹	11.1
Butylate	1.8
Carbaryl	4.2
Carbofuran	3.3
Chlorpyrifos	4.2
Cyanazine ¹	3.0
Cycloate	1.5
Dacthal	1.2
Diazinon	3.6
Diethatyl-ethyl	3.6
EPTC	4.5
Ethalfuralin ¹	2.4
Fonofos ¹	2.4
Hexazinone	5.7
Malathion	2.1
Methidathion	5.4
Methyl parathion ¹	4.2
Metolachlor	3.3
Molinate	2.7
Napropamide	7.2
Oxyfluorfen	4.2
Pebulate ¹	.6
Pendimethalin	2.4
Phosmet ¹	4.2
Piperonyl butoxide	3.3
Simazine	6.9
Sulfotep ¹	1.2
Thiobencarb	3.9
Trifluralin	3.0

¹Pesticide not detected during study
